Platypus ▲ (🦆 + 🐾 + 🐢)
@Platypusdefi

Dear Community,
We regret to inform you that our protocol was hacked recently, and the attacker took advantage of a flaw in our USP solvency check mechanism. They used a flashloan to exploit a logic error in the USP solvency check mechanism in the contract holding the collateral.

1:42 AM · Feb 17, 2023 · 172.5K Views

This was quite a simple exploit

It started with the taking a flash loan of 44M USDC which was deposited into Platypus. The resulting LP tokens were then used as collateral to borrow 41.7M USP.

The `emergencyWithdraw()` function only checks whether the user's position is *currently* solvent, but neglects to first check against any the effect of any borrowed funds. This allows the attacker to withdraw the supplied collateral while keeping the borrowed USP.

```

function emergencyWithdraw(uint256 _pid) public nonReentrant {
    PoolInfo storage pool = poolInfo[_pid];
    UserInfo storage user = userInfo[_pid][msg.sender];

    if (address(platypusTreasure) != address(0x00)) {
        (bool isSolvent, ) = platypusTreasure.isSolvent(msg.sender, address(poolInfo[_pid].lpToken), true);
        require(isSolvent, 'remaining amount exceeds collateral factor');
    }

    // reset rewarder before we update lpSupply and sumOfFactors
    IBoostedMultiRewarder rewarder = pool.rewarder;
    if (address(rewarder) != address(0)) {
        rewarder.onPtpReward(msg.sender, user.amount, 0, user.factor, 0);
    }

    // SafeERC20 is not needed as Asset will revert if transfer fails
    pool.lpToken.transfer(address(msg.sender), user.amount);

    // update non-dialuting factor
    pool.sumOfFactors -= user.factor;

    user.amount = 0;
    user.factor = 0;
    user.rewardDebt = 0;
}

```

The collateral withdrawn was then used to replay the flash loan, and the USP was swapped for other stablecoins.

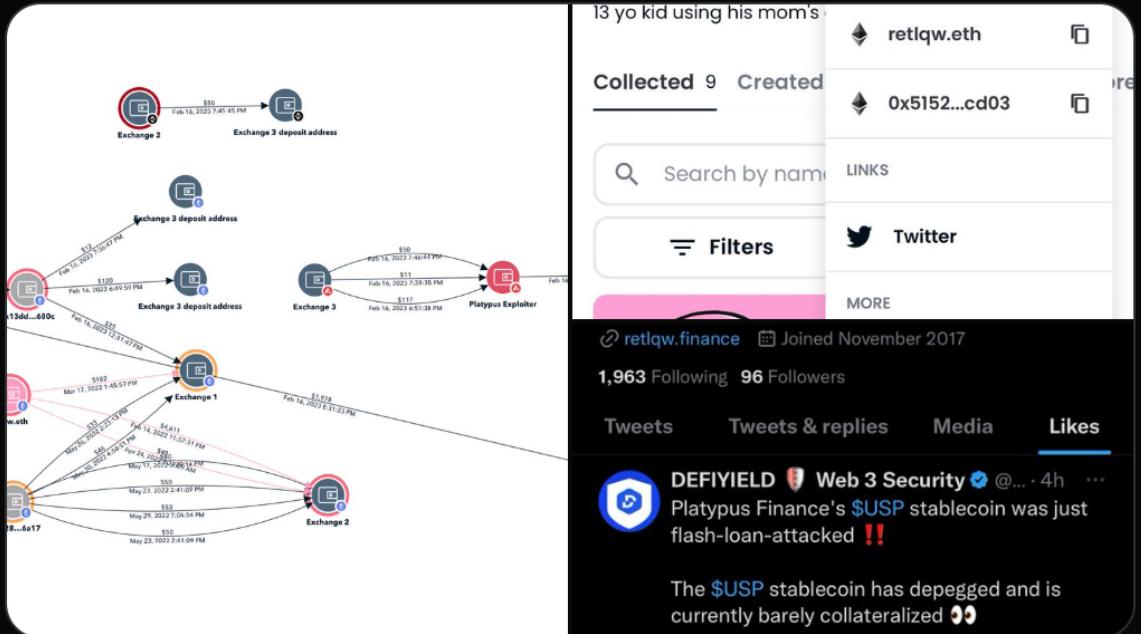

The attacker was however tracked down

ZachXBT ✅ @zachxbt · Feb 17

Replying to @zachxbt

I've reviewed your transaction history across multiple chains which lead me to your ENS address `reqlqw.eth`

Your OpenSea account links directly to your Twitter and you liked a Tweet about the Platypus exploit.

In a further twist funds were then taken from the attacker

details from Daniel Von Fange

"The attacker forgot to code any way collect the funds after stealing them, so the funds were locked in the attack contract. They also neglected Flash Loan 101 and allowed anyone to call the flash loan callback code. No check that they had started the flash loan."

"This allowed @BlockSecTeam and the project to retrigger the hack, but with one major twist - the project contracts had been upgraded to steal back from the attacker during the hack"

"The attack sequence involved taking flash loaned USDC, approving it, and depositing into the project. But during the retrigger, the attack code used its own stolen USDC to approve and deposit instead. The new project code simply took the attacker's USDC and ran with it."

Invocation Flow

```

Q Search address,function signature

```

3. Project laughs, takes funds

Wintermute Hack

Rekt [article](#)

Mudit Gupta [blog](#)

Evgeny Gaevoy CEO of Wintermute [tweets](#)

Attack vector

An admin address was compromised using the profanity vulnerability, Wintermute had removed funds from this address, but hadn't removed its admin role, which allowed the attacker to remove tokens from the vault.

The address was compromised because it had been created using the profanity tool, which was recently found to have a vulnerability.

Admin Address : 0x0000000fe6a514a32abdcdfcc076c85243de899b

It was created in this way to have large number of leading zeros which can save gas.

Evgeny Gaevoy explained :

"Last time we generated addresses this way was in June. We have since moved to a more secure key generation script. As we learned about the Profanity exploit last week, we accelerated the "old key" retirement

And then, due to an internal (human) error, a wrong function has been called and we blacklisted the router instead of the operator (contract that signs)

And such is a challenge of running a (truly) automated Market Maker in the Dark Forest.
You must automate processes as much as possible as multisig solutions are not applicable to our way of high speed trading "

The attack started with :

<https://etherscan.io/tx/0xeeecba26d5eb7939257e5b3e646e4bc597b73e256a89cb84a6dfc58de250d8a38> where Wintermute's hot wallet

(<https://etherscan.io/address/0x0000000fe6a514a32abdcdfcc076c85243de899b>)

started calling their vault contract

(<https://etherscan.io/address/0x0000000ae347930bd1e7b0f35588b92280f9e75>) to transfer tokens out to the hacker's contract

(<https://etherscan.io/address/0x0248f752802b2cfb4373cc0c3bc3964429385c26>)

PROFANITY VULNERABILITY

see 1inch [write up](#)

The author of the tool says :

"I've decided to also archive this repository to further reduce risk that someone uses this tool. The code will not receive any updates and I've left it in an uncomplilable state. Use something else! "

Evgeny Gaevoy finishes his tweets with
"And this is what we are planning to do. No lay-offs. No strategy changes. No emergency
fundraise. Not giving up on defi. Keep moving forward through this bear market with the
rest of you"

Nomad bridge Hack

Thanks to [Rekt](#) and [@samczsun](#) for their insights.

On 1st August 2022 the Nomad bridge was hacked and within 3 hours about \$190 M of funds were taken. The attack affected related projects such as EVMOS, Milkcomeda and Moonbeam.

August 1st 2022

The exploits unfolds...

The exploit was spotted as unusual activity by [@spreekaway](#), see this [thread](#)

Nomad bridge getting rugged??? Looks very very sus

10:37 PM · Aug 1, 2022 · Twitter Web App

It seemed that transactions were draining funds from the bridge, by sending 0.01 WBTC you could get 100 WBTC back

⌚ bitliq.eth	IN	📄 Nomad: ERC20 Bridge	0.01
📄 Nomad: ERC20 Bridge	OUT	0xe4a4df7e1689589efb0...	100
📄 Nomad: ERC20 Bridge	OUT	0xa8ecaf8745c56d5935c...	100

In theory the bridge was controlled by a transfer first being. proved and then a transaction could go through to process the movement of the funds.

So what *should* have been happening is that the messages submitted should have been proven, then included in a merkle tree whose root is stored and flagged as confirmed at a certain time.

What seemed to be happening is that messages were being processed that hadn't previously been confirmed. Once the initial exploiting transaction went through, anyone could simply submit a similar transaction to drain funds for themselves.

Subsequently there were many such transactions from exploiters, white hats , along with the use of MEV techniques to take advantage of the situation.

The top 3 exploiters were

0x56D8B635A7C88Fd1104D23d632AF40c1C3Aac4e3 (\$47M)

0xBF293D5138a2a1BA407B43672643434C43827179 (\$40M)

0xB5C55f76f90Cc528B2609109Ca14d8d84593590E (\$8M)

Some exploiters sent their funds through Tornado Cash to obfuscate the trail of funds.

As usual the exploited project appealed for people to return their funds.

Nomad have offered a deal to the exploiters asking for return of 90% of the funds, allowing the other 10% to be regarded as a bug bounty

Update: Nomad Bridge Hack Bounty

Nomad is announcing an **up to 10%** bounty to Nomad Bridge hackers where Nomad will consider any party who returns **at least 90%** of the total funds they hacked to be a white hat. Nomad will not pursue legal action against white hats. Funds must be returned to the official Nomad recovery wallet address:

0x94a84433101a10aeda762968f6995c574d1bf154.

Please be wary of impersonators and other scams.

Nomad is continuing to work with its community, law enforcement and blockchain analysis firms to ensure all funds are returned.

Exploit Details

The vulnerable contract is the Replica [contract](#)

This contract was upgraded and had the following initializer

```
function initialize(
    uint32 _remoteDomain,
    address _updater,
    bytes32 _committedRoot,
    uint256 _optimisticSeconds
) public initializer {

    __NomadBase_initialize(_updater);
    // set storage variables
    entered = 1;
    remoteDomain = _remoteDomain;
    committedRoot = _committedRoot;
    // pre-approve the committed root.
    confirmAt[_committedRoot] = 1;
    _setOptimisticTimeout(_optimisticSeconds);

}
```

It was initialized with the zero address

Transaction

```
Function: initialize(uint32 _remoteDomain, address _updater, bytes32 _committedRoot, uint256 _optimisticSeconds)

MethodID: 0xe7e7a7b7
[0]: 000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000
[1]: 000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000
[2]: 000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000
[3]: 000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000
```

```
function initialize(
    uint32 _remoteDomain,
    address _updater,
    bytes32 _committedRoot,
    uint256 _optimisticSeconds
) public initializer {
    __NomadBase_initialize(_updater);
    // set storage variables
    entered = 1;
    remoteDomain = _remoteDomain;
    committedRoot = _committedRoot;
```

```
// pre-approve the committed root.  
confirmAt[_committedRoot] = 1;  
_setOptimisticTimeout(_optimisticSeconds);  
}
```

In the initialize function, committedRoot is set to 0x00

```
committedRoot = _committedRoot;  
// pre-approve the committed root.  
confirmAt[_committedRoot] = 1;
```

and so

```
confirmAt[_committedRoot] = 1;
```

The first attempt to [exploit](#) the contract failed, it was an expensive failure costing 215 ETH.

② Block:	15259103	28418 Block Confirmations
② Timestamp:	④ 4 days 10 hrs ago (Aug-01-2022 09:32:59 PM +UTC)	⏱ Confirmed within 30 secs

② Gas Price:	0.000358358465198001 Ether	(358,358.465198001 Gwei)
② Ether Price:	\$1,630.62 / ETH	
② Gas Limit & Usage by Txn:	1,232,758	602,417 (48.87%)
② Gas Fees:	Base: 18.74448131 Gwei	

This was followed by the exploiting transaction calling the process function with the following arguments

```
        return true;  
    }
```

This line

```
require(acceptableRoot(messages[_messageHash]), "!proven");
```

checks the validity of the merkle root of of the messages

using this function

```
function acceptableRoot(bytes32 _root) public view returns (bool) {  
    // this is backwards-compatibility for messages proven/processed  
    // under previous versions  
    if (_root == LEGACY_STATUS_PROVEN) return true;  
    if (_root == LEGACY_STATUS_PROCESSED) return false;  
    uint256 _time = confirmAt[_root];  
    if (_time == 0) {  
        return false;  
    }  
    return block.timestamp >= _time;  
}
```

using the following constants declared earlier.

```
bytes32 public constant LEGACY_STATUS_NONE = bytes32(0);  
bytes32 public constant LEGACY_STATUS_PROVEN = bytes32(uint256(1));  
bytes32 public constant LEGACY_STATUS_PROCESSED = bytes32(uint256(2));
```

The line

```
uint256 _time = confirmAt[_root];
```

now returns 1 (remember in initialize, `confirmAt[0x00]` is set to 1)

You can check the return value of this function yourself on etherscan as I did :

5. acceptableRoot

_root (bytes32)

0x00

Query

↳ *bool*

[acceptableRoot(bytes32) method Response]

» *bool* : true

Thus any message sent to process would succeed !

Note

The audit report from Quanstamp is [available](#), their finding 'QSP-19 Proving With An Empty Leaf' is particularly relevant to this exploit, but perhaps not understood by the Nomad team.

Poly Network hack

Recap of function selectors

Encoding the function signatures and parameters

Example

```
pragma solidity ^0.8.0;

contract MyContract {

    Foo otherContract;

    function callOtherContract() public view returns (bool){
        bool answer = otherContract.baz(69,true);
        return answer;
    }
}

contract Foo {
    function bar(bytes3[2] memory) public pure {}
    function baz(uint32 x, bool y) public pure returns (bool r) {
        r = x > 32 || y;
    }
    function sam(bytes memory, bool, uint[] memory) public pure {}
}
```

The way the call is actually made involves encoding the function selector and parameters

If we wanted to call `baz` with the parameters `69` and `true`, we would pass 68 bytes total, which can be broken down into:

1. the Method ID. This is derived as the first 4 bytes of the Keccak hash of the ASCII form of the signature `baz(uint32,bool)`.

0xcdcd77c0:

2. the first parameter, a uint32 value 69 padded to 32 bytes

3. the second parameter - boolean true, padded to 32 bytes

In total

The Polynetwork Hack - \$600M stolen

Example messages to the attacker

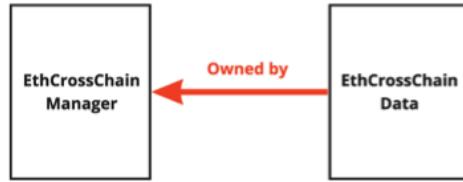

- Can I have some ETH? i been losing a lot of money Thank you
- Consider donating to public goods after all the pleasure you've got from using public infra 🌱
- ngmi
- Welcome to the crypto world. Fee Tips: Use tornado.cash to laundry your money ASAP.
- Forget your USDT. Forget your USDC.
- Swap tokens to ETH then deposit to tornado.cash . Good luck.
- Hi. Boos. Can. You. Give me eth thanks
- You can use Tornado for currency mixing
- DONT USE YOUR USDT TOKEN YOU VE GOT BLACKLISTED

- You can buy every pudgy penguin on opensea :)
 - Dad, this is my only asset. Please accept it
 - JOINING FOR EPIC SCREENCAP
 - Please gice me some eth
 - DONT USE YOUR USDT TOKEN
YOU VE GOT BLACKLISTED, god bless you
 - Remove liquidity from curve pool in form of DAI,
and exchange it for Eth and launder with Tornado
-

Exploit Details

Mismanagement of access rights between two contracts

EthCrossChainManager is an owner of EthCrossChainData,
= EthCrossChainManager can execute privileged functions!

_method is user defined
= can be set at will.

`bytes4(keccak256(abi.encodePacked(_method, "(bytes,bytes,uint64)"))),`
miro

5

Vulnerable Contract 2: EthCrossChainData

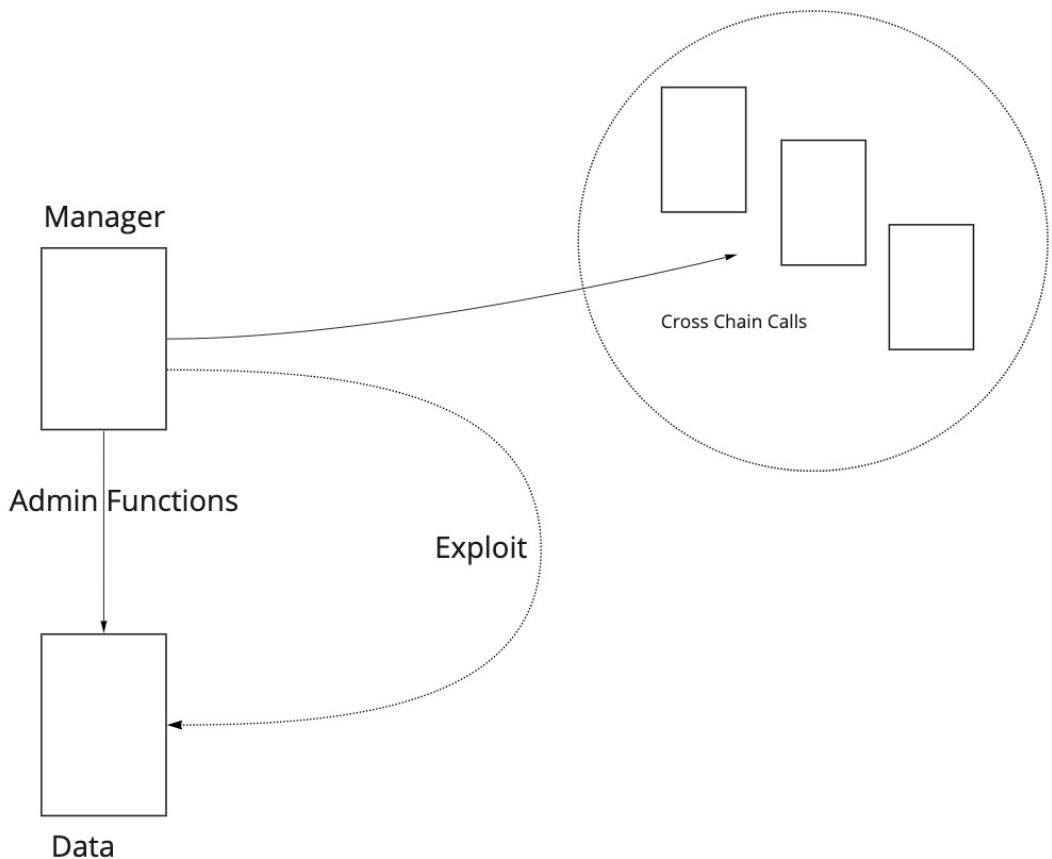

Very High Privileged contract ! ➔ Can only be called by its owners.

Set + manage list of “**Keepers**”
= list of public keys that manage the wallets in the underlying liquidity chain

➔ Keepers have the right to execute large transactions, transfer large amounts to other wallets.

Vulnerable function: `putCurEpochConPubKeyBytes`
= become a “Keeper”
Set the public key (passed as parameter) as a Keeper

10

Aiming to find X such that

$\text{Hash}(X, \text{bytes}, \text{bytes}, \text{uint64})$

=

$\text{Hash}(\text{putCurEpochConPubKeyBytes}, \text{bytes}) = 0x41973cd9$

The Brute Force solution was

$X = f1121318093$

The Attacker reconsiders

The attacker received a rather cryptic message

"Dont instant tornado funds, dont instant move blacklistable tokens to DAI/ETH? Insider confirmed!"

The attacker was looking at Tornado Cash and sent themselves a message

"Wonder why Tornado? Will miners stop me? Teach me please"

Then someone found a link between an address used by the attacker and some exchanges and tweeted

"Did the PolyNetwork Exploiter accidentally use the wrong sender address for this tx 0xb12681d9e? The sender address is tied to FTX, Binance, Okex accounts."

The hacker's attitude started to change, he suggested he could return "some tokens" or even abandon them, saying that they were "not so interested in the money".

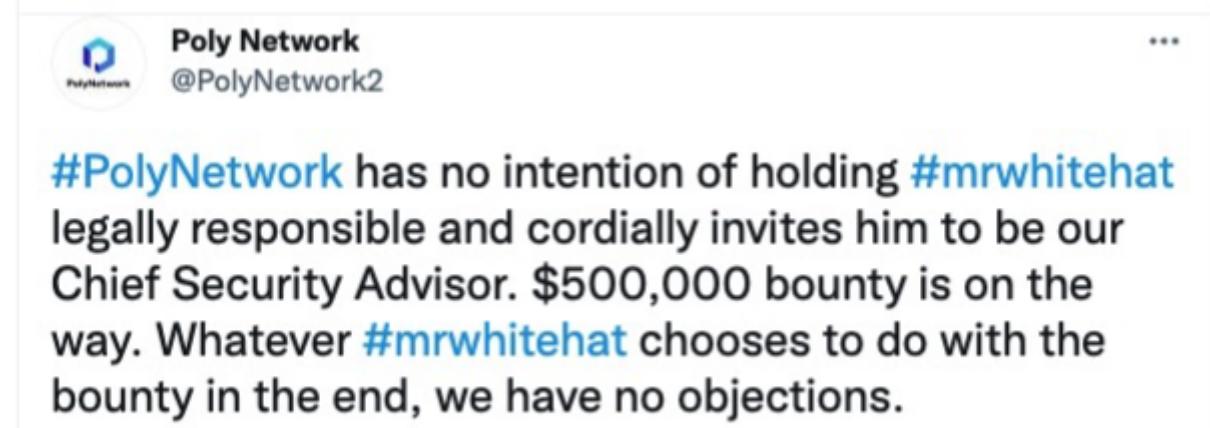

Followed by a suggestion : "What if I make a new token and let the DAO decide where the tokens go"

Finally the attacker messaged "Ready to return the fund!"

See this [spreadsheet](#) for all communications

The attacker starts to return the funds

PolyNetwork starts to refer to the attacker as 'Mr White Hat' and offer him a job and bounty

'We appreciate you sharing your experience and believe your action constitutes white hat behavior. But we can't touch user assets and Poly Network doesn't have its own token. Since , we believe your action is white hat behavior, we plan to offer you a \$500,000 bug bounty after you complete the refund fully. Also we assure you that you will not be accountable for this incident.

We hope that you can return all tokens as soon as possible. You can reserve the equivalent value of 500,000 USD in any assets to the current owner address. We will make up this part of the assets to Poly Network users.

Your contribution is very helpful to us. Again, we think this behavior is white hat behavior, therefor this 500,000 USD will be seen as completely legal bounty reward. We will also ensure that you will not be held accountable for this incident, and we will publicly express our gratitude to you.'

Lasttime Refund	Chain	Hacker Address	Hack	Refund

A number of rather lengthy messages follow the return of the funds

Q & A, PART TWO:

Q: WHAT REALLY HAPPENED 30 HOURS AGO?

A: LONG STORY.

BELIEVE IT OR NOT, I WAS _FORCED_ TO PLAY THE GAME.

THE POLY NETWORK IS A SOPHISTICATED SYSTEM, I DIDN'T MANAGE TO BUILD A LOCAL TESTING ENVIRONMENT. I FAILED TO PRODUCE A POC AT THE BEGINNING. HOWEVER, THE AHA MOMEMNT CAME JUST BEFORE I WAS TO GIVE UP. AFTER DEBUGGING ALL NIGHT, I CRAFTED A _SINGLE_ MESSAGE TO THE ONTOLOGY NETWORK.

I WAS PLANNING TO LAUNCH A COOL BLITZKRIEG TO TAKE OVER THE FOUR NETWORK: ETH, BSC, POLYGON & HECO. HOWEVER THE HECO NETWORK GOES WRONG! THE RELAYER DOES NOT BEHAVE LIKE THE OTHERS, A KEEPER JUST RELAYED MY EXPLOIT DIRECTLY, AND THE KEY WAS UPDATED TO SOME WRONG PARAMETERS. IT RUINED MY PLAN.

I SHOULD HAVE STOPPED AT THAT MOMENT, BUT I DECIDED TO LET THE SHOW GO ON! WHAT IF THEY PATCH THE BUG SECRETLY WITHOUT ANY NOTIFICATION?

HOWEVER, I DIDN'T WANT TO CAUSE _REAL_ PANIC OF THE CRYPTO WORLD. SO I CHOSE TO IGNORE SHIT COINS, SO PEOPLE DIDN'T HAVE TO WORRY ABOUT THEM GOING TO ZERO. I TOOK IMPORTANT TOKENS (EXCEPT FOR SHIB) AND DIDN'T SELL ANY OF THEM.

Q: THEN WHY SELLING/SWAPPING THE STABLES?

A: I WAS PISSED BY THE POLY TEAM FOR THEIR INITIAL REONSE.

THEY URGED OTHERS TO BLAME & HATE ME BEFORE I HAD ANY CHANCE TO REPLY! OF COURSE I KNEW THERE ARE FAKE DEFI COINS, BUT I DIDN'T TAKE IT SERIOUSLY SINCE I HAD NO PLAN LAUNDERING THEM.

IN THE MEANWHILE, DEPOSITING THE STABLES COULD EARN SOME INTEREST TO COVER POTENTIAL COST SO THAT I HAVE MORE TIME TO NEGOTIATE WITH THE POLY TEAM.

Arbitrum critical vulnerability

A critical vulnerability that was spotted in time, caused by too much optimisation.

See [writeup](#) from white hat.

A bridge address is used to receive funds deposited in Arbitrum, it is vital that this address is set up correctly and cannot be switched to a malicious contract.

Upgradeable contracts can go very wrong if the initialize function isn't adequately secured.

In this contract there were 2 flags in storage to check if initialize had been run or was running

```
modifier initializer() {
    // If the contract is initializing we ignore whether _initialized is set in order to support multiple
    // inheritance patterns, but we only do this in the context of a constructor, because in other contexts the
    // contract may have been reentered.
    require(_initializing ? _isConstructor() : !_initialized, "Initializable: contract is already initialized");

    bool isTopLevelCall = !_initializing;
    if (isTopLevelCall) {
        _initializing = true;
        _initialized = true;
    }

    if (isTopLevelCall) {
        _initializing = false;
    }
}
```

The initialize function also had check to see if the bridge address was already set

```
105     function initialize(IBridge _bridge, ISequencerInbox _sequencerInbox)
106         external
107             initializer
108             onlyDelegated
109         {
110             -         if (address(bridge) != address(0)) revert AlreadyInit();
111             bridge = _bridge;
112             sequencerInbox = _sequencerInbox;
113             allowListEnabled = false;
114             __Pausable_init();
115         }
```

Unfortunately that check had been taken out to reduce gas, but things would still be ok, as long as the flags were still set...

A further optimisation cleared out the first 3 storage slots after upgrade

```
function postUpgradeInit(IBridge _bridge) external onlyDelegated onlyProxyOwner {
    uint8 slotsToWipe = 3;
    for (uint8 i = 0; i < slotsToWipe; i++) {
        assembly {
            sstore(i, 0)
        }
    }
    allowListEnabled = false;
    bridge = _bridge;
}
```

So, an attacker could now call the initialize function, setting the address of the bridge contract to a contract that they control, and thus receive any ETH that users deposit.

Security / Best Practices

ConsenSys Best Practices

General

- Prepare for Failure
- Stay up to Date
- Keep it Simple
- Rolling out
- Blockchain Properties
- Simplicity vs. Complexity

Precautions

- General
- Upgradeability
- Circuit Breakers
- Speed Bumps
- Rate Limiting
- Deployment
- Safe Haven

Solidity Specific

- Assert, Require, Revert
- Modifiers as Guards
- Integer Division
- Abstract vs Interfaces
- Fallback Functions
- Payability
- Visibility
- Locking Pragmas
- Event Monitoring
- Shadowing
- tx.origin
- Timestamp Dependence
- Complex Inheritance
- Interface Types
- EXTCODESIZE Checks

Token Specific

- Standardization
- Frontrunning
- Zero Address
- Contract Address

Documentation

- General
- Specification
- Status
- Procedures
- Known Issues
- History
- Contact

Attacks

- Reentrancy
- Oracle Manipulation
- Frontrunning
- Timestamp Dependence
- Insecure Arithmetic
- Denial of Service
- Griefing
- Force Feeding

General Security Best Practices

- Before Using Yul, Verify YOUR assembly is better than the compiler's
- Using Vanity Addresses with lots of leading zeroes
Why? Well if you have 2 addresses - 0x000000a4323... and 0x000000000f38210 because of the leading zeroes you can pack them both into the same storage slot, then just prepend the necessary amount of zeroes when using them. This saves you storage when doing things such as checking the owner of a contract. (But dont use the profanity tool to create this, see the Wintermute hack below.)
